# Low 25-Hydroxyvitamin D Is Associated with Increased Mortality in Female Nursing Home Residents

Medizinische Universität Graz

**J Clin Endocrin Metab.** First published ahead of print February 8, 2012 as doi:10.1210/jc.2011-3043

Stefan Pilz, Harald Dobnig, Andreas Tomaschitz, Katharina Kienreich, Andreas Meinitzer, Claudia Friedl, Doris Wagner, Claudia Pischwanger-Sölkner, Winfried März, and Astrid Fahrleitner-Pammer

**Design, Setting, and Participants:** This is a prospective cohort study among elderly female patients (age >70 yr) recruited from 95 nursing homes in Austria.

**Appeal for Vitamin D Therapy**

We examined 961 study participants (age  $83.7 \pm 6.1$  yr) *Dtsch Arztebl Int* 2012; 109(19)

During a mean follow-up time of  $27 \pm 8$  months, 284 patients died.

**TABLE 2.** Hazard ratios (with 95% confidence intervals) for mortality according to 25(OH)D quartiles

|                    | 1st quartile     | 2nd quartile     | 3rd quartile     | 4th quartile   |
|--------------------|------------------|------------------|------------------|----------------|
| Range (nmol/liter) | <14.0            | 14.0–17.5        | 17.6–25.5        | >25.5          |
| Crude              | 1.74 (1.25–2.43) | 1.41 (1.00–1.98) | 1.08 (0.75–1.55) | 1.00 reference |
| Model 1            | 1.49 (1.07–2.10) | 1.32 (0.93–1.86) | 1.03 (0.72–1.48) | 1.00 reference |
| Model 2            | 1.45 (1.03–2.06) | 1.25 (0.88–1.79) | 1.08 (0.75–1.56) | 1.00 reference |
| Model 3            | 1.57 (1.10–2.23) | 1.30 (0.90–1.86) | 1.16 (0.80–1.68) | 1.00 reference |
| Model 4            | 1.88 (1.28–2.76) | 1.49 (1.02–2.16) | 1.31 (0.90–1.93) | 1.00 reference |
| Model 5            | 1.56 (1.01–2.40) | 1.21 (0.80–1.84) | 1.32 (0.88–1.97) | 1.00 reference |

Model 1 was adjusted for age. Model 2 was adjusted for age, BMI, and albumin. Model 3 was adjusted for covariates of model 2 plus creatinine clearance, glycated hemoglobin, arterial hypertension, and coronary artery disease. Model 4 was adjusted for covariates of model 3 plus serum calcium, serum phosphate, and PTH. Model 5 was adjusted for covariates of model 4 plus knee extensor strength and mobility status.

# META-ANALYSIS

Medizinische Universität Graz

## Key results

This review suggests that vitamin D<sub>3</sub> may reduce mortality, showing that **about 150 participants need to be treated over five years for one additional life to be saved.** We found comparable effects of vitamin D<sub>3</sub> in studies that included only women compared with studies including both women and men. Vitamin D<sub>3</sub> also seemed to decrease cancer mortality, showing a reduction in mortality of 4 per 1000 persons treated for five to seven years. We also observed adverse effects to vitamin D such as renal stone formation (seen for vitamin D<sub>3</sub> combined with calcium) and elevated blood levels of calcium (seen for both alfacalcidol and calcitriol). In conclusion, we found some evidence that vitamin D<sub>3</sub> seems to decrease mortality in elderly people not dependent on help or living in institutional care.

## Quality of the evidence

A large number of study participants left the trial before completion, and this raises concerns regarding the validity of the results. **More randomised clinical trials are needed** on the effects of vitamin D<sub>3</sub> on mortality in younger, healthy persons, as well as in elderly community-dwelling and institutionalised persons without apparent vitamin D deficiency.

# Uncertain Verdict as Vitamin D Goes On Trial

—KAI KUPFERSCHMIDT

21 SEPTEMBER 2012 VOL 337 SCIENCE

Medizinisc

## Disease Prevention: Vitamin D Trials

ALTHOUGH THERE IS A DEBATE ON CUT-OFFS for appropriate vitamin D supplementation (“Uncertain verdict as vitamin D goes on trial,” K. Kupferschmidt, News, special section on Disease Prevention, 21 September, p. 1476), clinicians universally agree that vitamin D deficiency is detrimental for bone health (1). We also know that vitamin D overdosing can be toxic. What quantity will prevent both deficiency and toxicity?

To find the ultimate vitamin D dose and to evaluate its effectiveness, researchers should learn from randomized controlled trials (RCTs) of drugs for diabetic or hypertensive patients, who were usually treated with the goal of achieving well-defined targets, such as certain HbA1c or blood pressure levels. In the case of vitamin D, this would mean performing RCTs in individuals with overt vitamin D deficiency and using doses to achieve optimal vitamin D levels.

Instead of performing these kinds of RCTs, the design of the ongoing vitamin D trials resembles previous (disappointing) vitamin trials, which attempted to establish a dose that should fit for the entire population (2). If the current vitamin D trials fail, we will ask ourselves why we did not perform RCTs exclusively in vitamin D-deficient patients rather than attempting to base conclusions on a heterogeneous population. Subgroup analyses of existing trials will not satisfy health authorities.
