

# Genomic Selection for Dwarf Bunt Resistance in Wheat

22<sup>nd</sup> International Workshop on Bunt and Smut Diseases of Cereals

Will Krause

Advisor: Dr. Margaret Krause

UtahStateUniversity

*June 13, 2023*

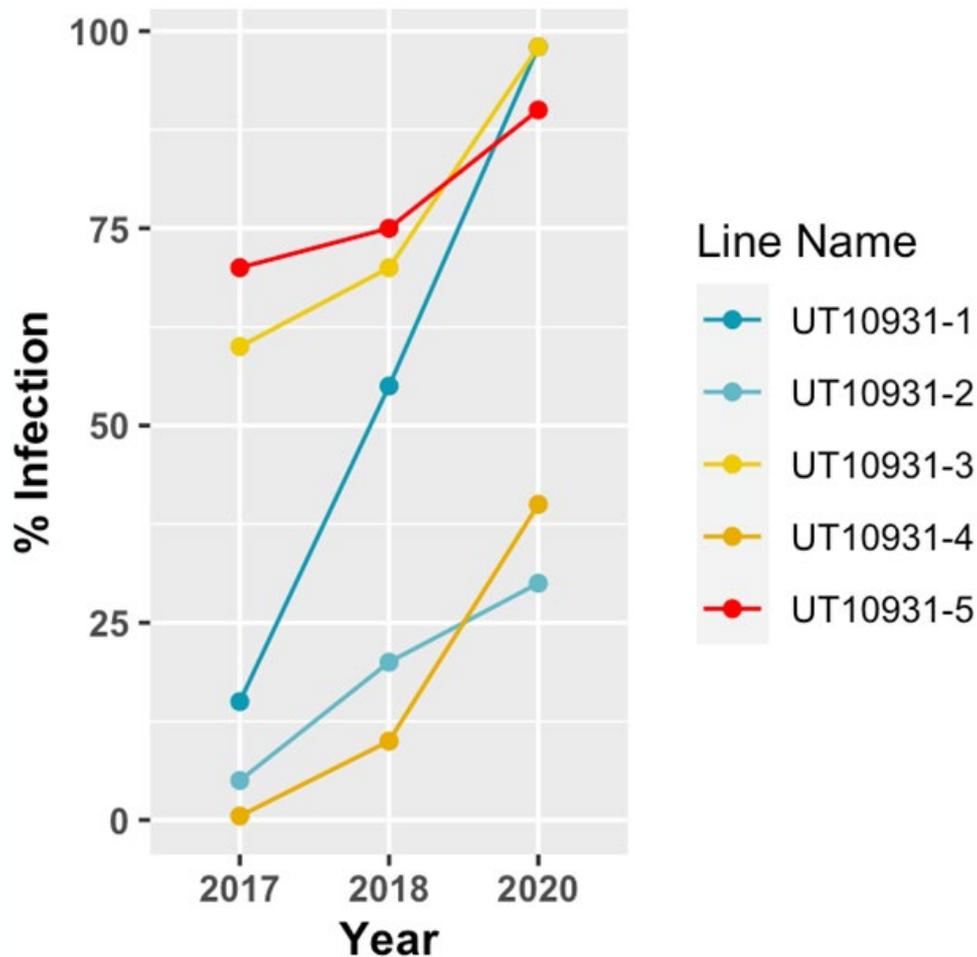

# Disease History and Significance

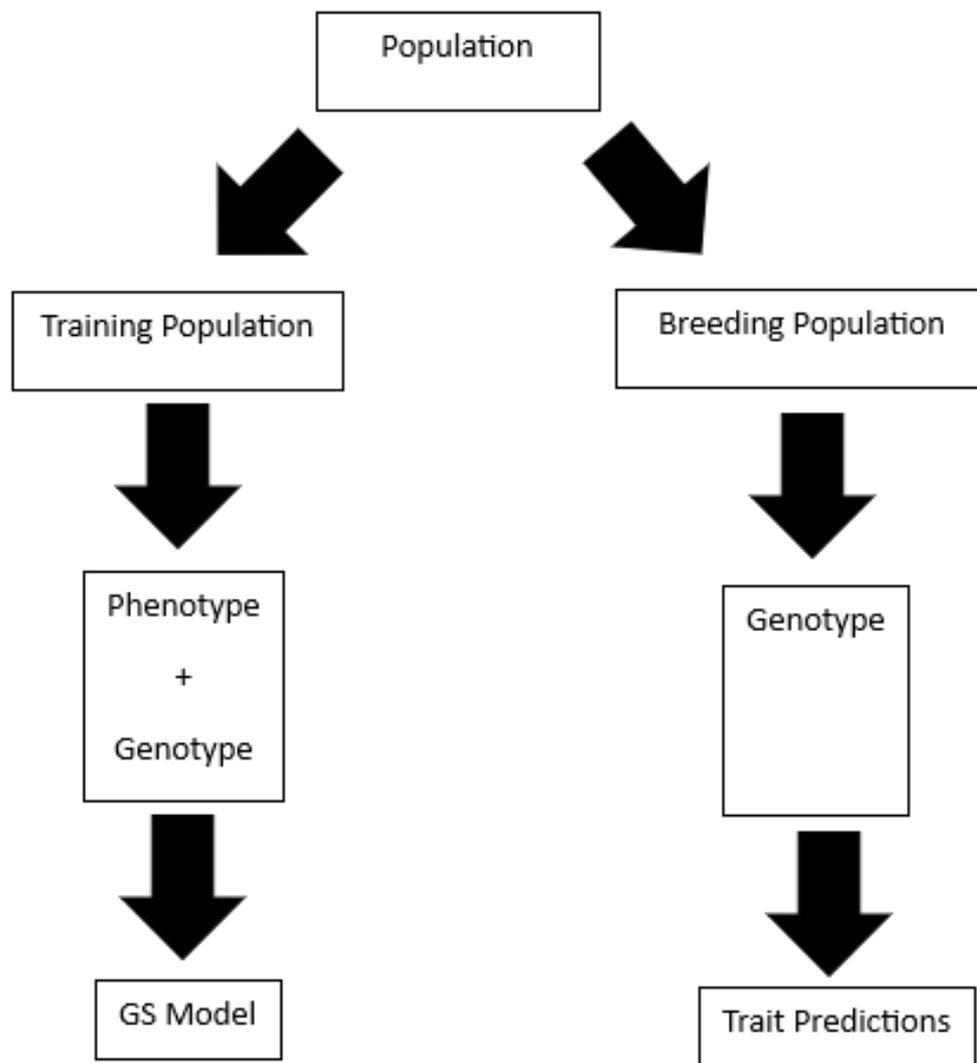

- Scientific name : *Tilletia controversa*
- Common name : dwarf bunt
- First identified as a problem
  - 1930's in Utah
- Importance of management
  - Organic production : 30% of Utah acreage
- USU varieties
  - Relief 1934
  - PI 178383

# Objective

- Test genomic selection's ability to predict dwarf bunt resistance in winter wheat
- Good vs poor infection
- Emergence, weather, snow cover

# Wheat Population

- 384 diverse inbred lines of winter wheat with varying levels of resistance
- Public sector programs from Intermountain West
- Comprise the “Training Population”
- Genotypic data : two types of SNP genotyping platforms
- Phenotypic data : 2022 and 2023 dwarf bunt ratings

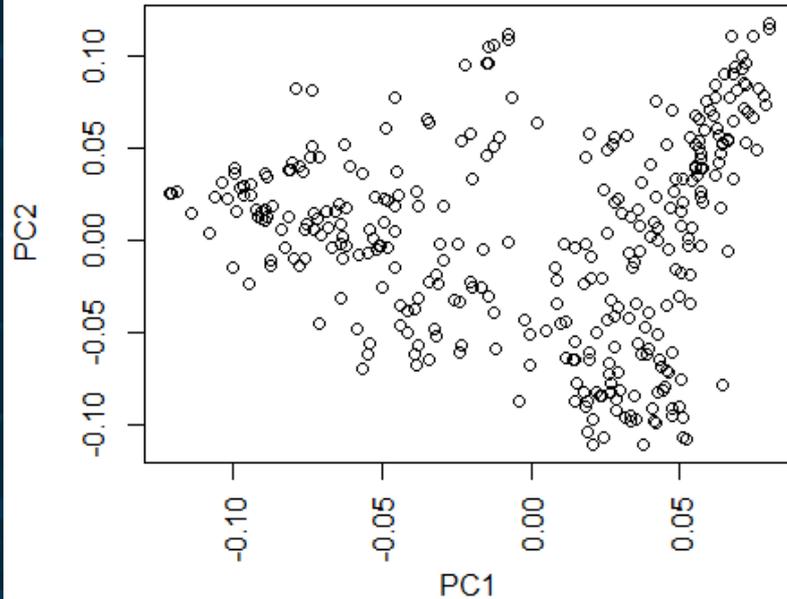

# How does genomic prediction accuracy differ between SNP genotyping platforms?

- Genotyping by Multiplexed Sequencing (GMS) : 1519 SNPs
  - Dr. Deven See : USDA Pullman, Washington USA
- 90k Illumina iSelect SNP chip : 3330 SNPs

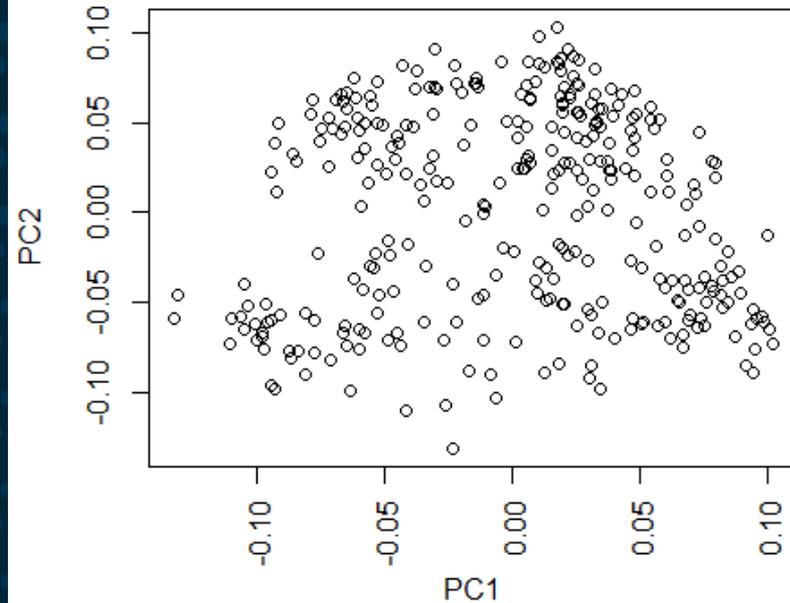

# Principal Component Analysis

90K PCA

GMS PCA

# Phenotypic Data

- Disease ratings
  - Ratio of infected vs uninfected spikes

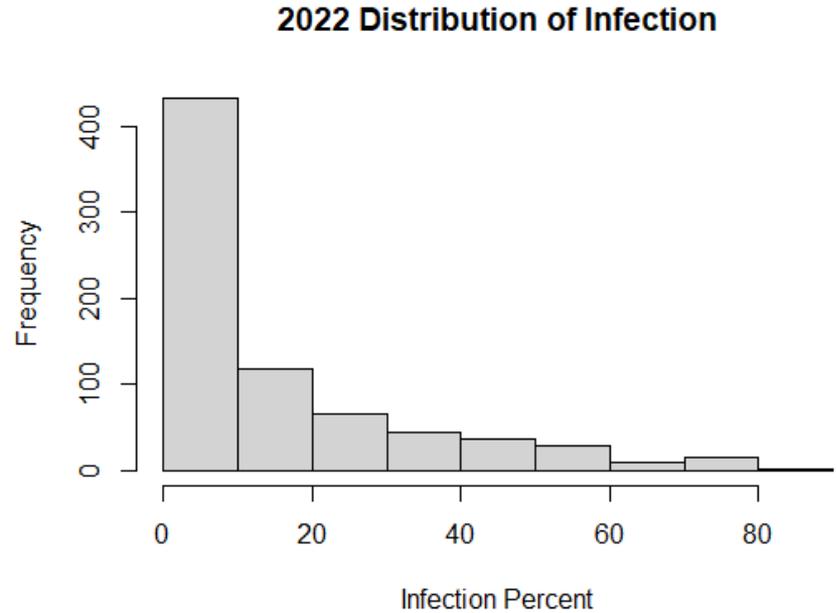

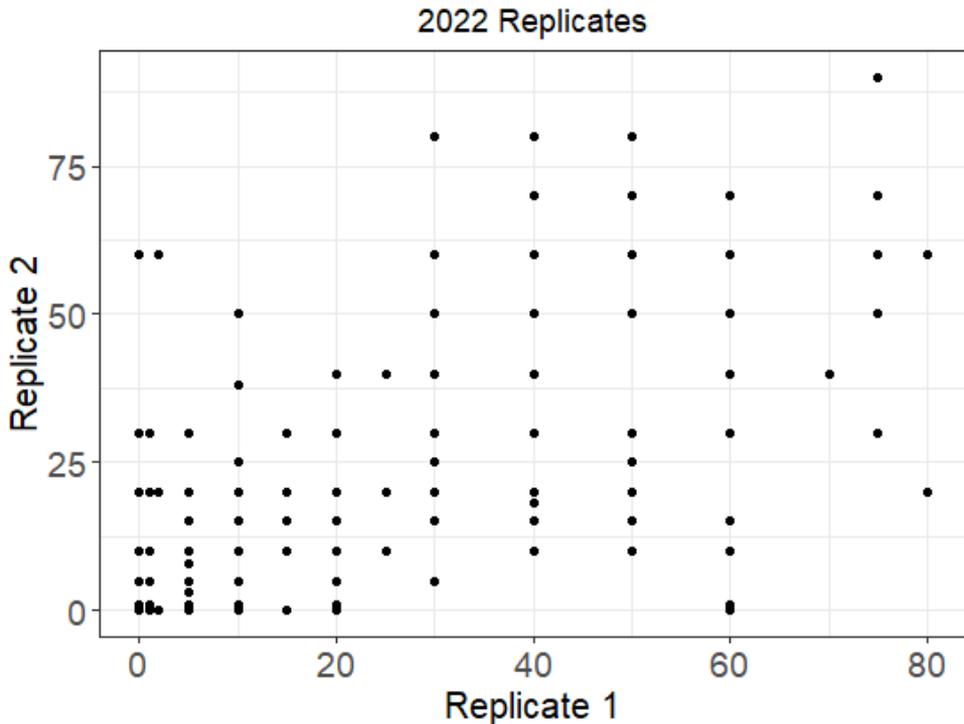

## Trial Inoculation

- Dwarf Bunt spores are inoculated with 1g of spores per 1.2m row

# Dwarf Bunt Infection Data

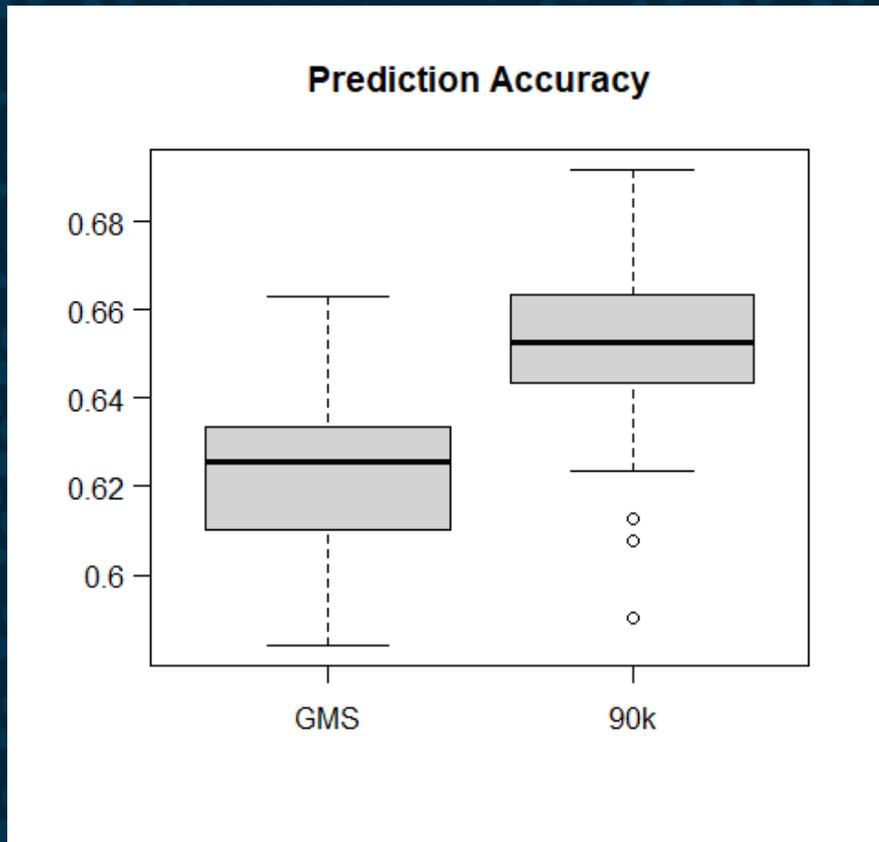

- Line mean heritability of 0.84
  - Calculated from replicated field data
  - Values from 0 to 1

# Analysis

$$\frac{V_g}{V_g + (V_e / n.rep)}$$

# Prediction Accuracy

# Conclusion and Future Work

- High line mean heritability : Replicates show similar infections
- High prediction accuracy : Model reliably predicts infection
- Future work
  - Additional PCA analysis
  - Collect 2023 dwarf bunt infection data
  - Repeat analysis for 2023 data
  - Genome Wide Association Study
  - Models incorporating high effect markers as fixed effects
